summary)

Abstract: The base content of tar obtained from sapropelite coal from the Spizn swamp, Dobel rayon, Latvian SSR, has been investigated; 9-10% bases were found to be present in the tar. It is shown that the bases consist principally of compounds of the pyridine and quinoline series. No primary means were found; secondary means were determined to be present. The author have investigated the pyridine-picoline fraction. Five pyridines have been separated and identified: pyridine, α -, β -, γ -

REPORT: Ponomarev, Ya. A. Fedotkin, L. A. Synthesis of 5-bromo quinoline

RESEARCH: Synthesis of 5-bromo quinoline

TEXT: The synthesis of 5-bromo quinoline from naphthalene (Ref. 1) is a difficult task. Afterward, the 5-bromo quinoline must be separated with a large quantity of the distillate. Besides, an about 10% yield of 5-bromo quinoline is formed the complete separation of 5-bromo quinoline from the distillate. The yield in pure 5-bromo quinoline in this synthesis is more than 10-20% (calculated for naphthalene). Also, the synthesis of 5-bromo quinoline by diazotization of 5-aminonaphthalene and 5-bromo quinoline for the diene group (Ref. 2) show several shortcomings. The authors of the present paper, on the basis of 5-aminonaphthalene, naphthalene, 5-aminonaphthalene and 5-bromo quinoline (Ref. 3), 5-aminonaphthalene and 5-bromo quinoline (Ref. 4) and 5-bromo quinoline (Ref. 5) have obtained easily by oxidation of 5-aminonaphthalene with nitric acid in the

Card 1/3

presence of ammonium bisulfite. G. I. Hibberley (Ref. 7) improved this method, and was able to raise the yield of 5-bromo quinoline to 10-15%. The authors used this method for the preparation of 5-bromo quinoline. The synthesis of 5-bromo quinoline derived in naphthalene is complicated as follows: 5-aminonaphthalene is acetylated in benzene solution with acetic anhydride. 5-aminonaphthalene which results in good yield is not isolated but brominated in the resultant reaction mixture at 0-5°C. In this way, 5-bromo-4-acetylnaphthalene is obtained in yields up to 90%. By treatment with hydrochloric acid, the acetyl group is split off. The resulting 5-bromo-4-aminonaphthalene is diazotized in sulfuric acid solution at -10°C. By reaction with copper powder and alcohol, the diene group is replaced by hydrogen, and 5-bromoquinoline results as a product in a yield of 40-50%. In an experimental part, the total course of synthesis is described in detail. The scheme of the synthesis is given as well. There are 11 references, 4 of which are Soviet.

PURPOSE: This book is intended for metallurgical engineers, research workers in metallurgy, and may also be of interest to students of advanced courses in metallurgy.

CONTENTS: This book, consisting of a number of papers, deals with the properties of heat-resistant alloys. Each of the papers is devoted to the study of the properties of alloys under various conditions of service. The effects of various alloying elements on the properties of alloys are studied. Properties of various alloys are studied. The book also contains a bibliography of articles on the subject of heat-resistant alloys. The book is written in a clear and concise style, and is suitable for use as a reference work. The book is written in Russian, and is suitable for use as a reference work. The book is written in Russian, and is suitable for use as a reference work.

TITLE: The Long-term Strength of Boiler Steels under Variable
Temperature Conditions

PERIODICAL: Teploenergetika, 1959, Nr 9, pp 57-63 (USSR)

ABSTRACT: Existing methods of calculating the strength of parts operating under creep conditions are based on permissible stresses at constant temperatures. In practice, the temperature may be very variable, as in starting up boilers. The materials investigated were steam/water tubes of steel 12KhMF, 273 x 32 mm diameter, and steel 1Kh18N12T, 219 x 27 mm diameter. The chemical composition, heat treatment, and mechanical properties of the steel are given in Table 1. Steel 12KhMF consists of ferrite and pearlite, and steel 1Kh18N12T is of normal austenitic structure. The long-term strength tests were made on normal cylindrical specimens 10 mm diameter and 100 mm long. The first stage consisted of preliminary tests at constant temperature, and the results are given in Table 2. A temperature of 565 °C was chosen as normal for steel 12KhMF and 600 °C for steel 1Kh18N12T. Most of the tests were made at these temperatures to obtain reliable data

Card 1/5

SOV/96-59-9-10/22

The Long-term Strength of Boiler Steels under Variable Temperature Conditions

for the ultimate strength at 100 000 hours. Fewer tests were made at higher temperatures because the long-term strength of both steels is already very well known. At other temperatures agreement with published data was satisfactory. The different types of temperature cycling used are described and typical temperature cycle graphs are illustrated diagrammatically in Fig 1. The results of tests at variable temperatures are given in Table 3. It will be seen that overheating reduces the long-term strength of steel, particularly as the temperature and the time are increased. The plasticity at failure is practically the same as in constant-temperature tests. The methods used to work out the results and to summate the loss of life at different temperatures are explained. Existing methods of determining the time to failure under variable temperature conditions require complicated analytical calculations, and simpler and more convenient procedures are required. The procedure evolved for evaluating the influence of temperature cycling made use of the parametric relationship proposed

Card 2/5

SOV/96-59-9-10/22

The Long-term Strength of Boiler Steels under Variable Temperature Conditions

by Larson and Miller. This involves Eq (1), to determine the time to failure at one temperature from test data obtained at another temperature. This formula can be used to translate to a reference temperature exposure times at another temperature. A graphical method of working out the results was used, auxiliary lines being drawn on the parametric graph according to the temperature stages of the long-term strength test. The results of constant temperature tests were used to construct generalised parametric relationships of the type shown graphically in Fig 2 for steel 12KhMF. The rectangles on Fig 2 indicate the limits of scatter of the long-term strength tests results at variable temperatures. The corresponding numerical values are given in Table 4. Analysis of the graphs given in Fig 1 and the data in Table 4 shows that the test results at variable temperature coincide satisfactorily with the generalised straight line. Therefore, the parametric relationship may be used to evaluate the influence of overheating on the long-term strength. The weak point in the method is the selection of the coefficient c in Eq (1), and

Card
3/5

SOV/96-59-9-10/22

The Long-term Strength of Boiler Steels under Variable Temperature Conditions

after some consideration of this point it is recommended to use values of c from 21 to 27 for steel 12KhMF and from 8 to 19 for steel 1Kh18N12T. It is evident that the value of 20 recommended by Larson and Miller should not be used for all materials. A graphical method was developed to determine the time to failure and long-term ultimate strength under variable temperature conditions. The procedure is explained and the generalised diagrams for the two steels examined are given in Figs 3 and 4. It is claimed that the graphical method has the advantages of simplicity and convenience in finding the time to failure at variable temperature by means of nomograms; moreover, the long-term ultimate strength can easily be determined. When using the graphical method it is not necessary to know the shape of the

AUTHOR: Fedotova, L.I., Candidate of Technical Sciences
TITLE: Creep-resistance of a pearlitic steel under conditions
of cyclic temperature variation

PERIODICAL: Teploenergetika, no. 2, 1962, 56 - 59

TEXT: The pearlitic steel 12XMF (12KhMF) has recently found wide application as a material of construction for more responsible parts of boiler plant. However, it has been found at several power stations that the material of steam-conduit pipes had a low impact strength. This has given rise to doubts regarding the suitability of the steel 12KhMF for this application - hence the present investigation carried out on specimens cut from a tube (273 x 36 mm) having the following composition (%): C 0.12; Mn 0.50; Si 0.31; S 0.026; P 0.013; Cr 1.25; Mo 0.30, V 0.16. Specimens in a brittle condition were obtained by normalizing the steel for 30 min at 980 °C and 2 hours tempering at 650 °C. Electron-microscope examination of the microstructure showed that whereas steel in the ductile

Card 1/10

Creep-resistance of

S/096/62/000/002/002/008
E193/E383

condition had clearly defined grain boundaries free from precipitated phases, the structure of the brittle specimens was characterized by the presence of secondary-phase particles distributed mainly in a chain-like fashion along the grain boundaries. The mechanical properties of both types of material are given in Table 1. Creep tests were carried out under conditions of cyclic temperature variation, one cycle consisting of 24 hours at a temperature 25 or 15 °C below 570 °C, followed by 24 hours at a temperature 25 or 15 °C above 570 °C. The results are reproduced (in logarithmic coordinates) in Fig. 4, ✓

where the stress (kg/mm^2) is plotted against time-to-rupture (hours), graphs a and b representing, respectively, the results of tests under 555-585-555 and 545-595-545 °C cycles; Curves 1-5 relate to specimens in: 1 - ductile condition; 2 - brittle condition; 3 - brittle condition (notched specimens); 4 - brittle condition (unnotched specimens) and 5 - brittle condition (notched specimens); the broken parts of the curves were obtained by extrapolation. After each time-to-rupture

Card 2/10

Creep-resistance of

S/096/62/000/002/002/008
E193/E383

test, the material was subjected to mechanical tests at room temperature. The results of these tests are given in Table 4. The microstructure of the ruptured specimens was also examined and the composition of the carbide phases (separated by electrolytic dissolution) was determined. The results are given in Table 5. It will be seen that in the case of ductile material, its solid solution after the tests had been found denuded of carbide-forming constituents, whereas the composition of carbides in the brittle material remained practically unaltered. Examination of the microstructure of ruptured specimens showed that the lamellar character of pearlite and absence of precipitated phases along the grain boundaries in ductile material were hardly affected by cyclic temperature variation under stress. The precipitates of secondary phases, present along the grain boundaries in the brittle material before the ageing tests, could be observed also after the tests; in addition, there was evidence of fragmentation of grains and formation of blocks. The fracture of the ductile material was intracrystalline and was preceded by considerable plastic deformation.

Card 3/40

S/096/62/000/002/002/008
E193/E383

Creep-resistance of

The following general conclusions were reached: 1) under conditions of the present investigation (stress and thermal cycling), plasticity of the steels studied in the brittle condition can fall to 1-2%. On the other hand, the value of stress leading to fracture of the brittle material in 100 000 hours is higher than that for steel in the ductile condition. This means that on the one hand it may be dangerous to use steam-conduit pipes in the initially brittle condition, i.e. with $a_K < 1 \text{ kgm/cm}^2$ and, on the other hand, it may not be advisable to aim at the highest possible initial value of a_K , which raises the problem of determining its optimum value. 2) Stress risers decrease the resistance to creep of the steel studied under conditions of cyclic temperature variation, this effect being more pronounced at high values of the applied stress. 3) The impact strength of ductile steel, stressed under conditions of cyclic temperature variation, slightly increases.

TITLE: On the effect of temperature variation upon the endurance of steel
12X MΦ(12KhMF)

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 3, 1962, 28, abstract 3I168
(V sb. "Ekspluatats. nadezhnost' metalla parosilovykh ustanovok".
Moscow - Leningrad, Gosenergoizdat, 1959, 83-89)

TEXT: An investigation was carried out on specimens of boiler steel
12KhMF, cut out from a steam pipe with 173 x 32 mm diameter after normalizing
at 960 - 980°C and subsequent tempering at 740 - 760°C. The endurance tests
were carried out on ИП-2 (IP-2) machines at the rated temperature of 565°C and
stresses of 15, 18, and 20 kg/mm². Besides tests at constant and varying
temperatures at 565, 575 (variation 10°C), 590 (variation 25°C), and 615°C
(variation 50°C), combined tests were carried out: after testing the specimens
for a definite period of time at the rated temperature, they were heated up to
a higher temperature (the variation prescribed) and were brought up to failure.
In each series of tests the duration of the soaking at the rated temperature

Card 1/2

On the effect of temperature variation ...

S/137/62/000/003/123/191
A060/A101

(before increasing up to a higher temperature) constituted 75, 50, and 25% of the time till failure at 565°C. The creep curves during the transition to the higher temperature sharply change their slope, and this the more sharply, the greater is the size of the temperature variation. It is noted that the ductility of the 12KhMF steel under combined tests is practically not lowered at all. An investigation of the possibility of applying the Larson-Miller temperature-time dependence for estimating the effect of temperature variations has shown that when the value of the coefficient C is correctly chosen this dependence is valid. It is confirmed that the value of C varies between wide limits as a function of varying the testing conditions (in the tests carried out C varies between 15 and 27). As the criterion for the correct choice of the value of C it is proposed to apply the condition of coincidence of the endurance limits determined by the parametric and the classical methods.

TOPIC TAGS: steel, endurance limit, impact strength, aging process/ 12Kh1MF
steel, 15Kh1MF steel

ABSTRACT: The reliability of two types of steels, 12Kh1MF and 15Kh1MF, was investigated in connection with their use as collector tube metals in a 300 Mw unit. The 12Kh1MF steel tube was quenched in 950C oil and annealed at 740-750C for 9 hours. The 15Kh1MF steel tube was standardized at 1050-1100C and annealed at 740-750C for 15 hours. Their impact strength remains unchanged up to a 620C temperature increase. Their strength characteristics at room temperature also remained unchanged in the aging process at 595C. Curves of endurance strength limit σ for both steels at 600 and 620C were found to be significantly lower

Card 1/3

I. 22159-65

ACCESSION NR: AP5002204

than σ at 585C for the 12Kh1MF steel (by about 3 kg/mm²). Because of this low σ , under equal conditions the 12Kh1MF steel tube should be much thicker than the 15Kh1MF steel tube. These allowable stresses are given in Table 1 of the Enclosure. Orig. art. has: 7 tables and 2 figures.

TITLE: Higher dialkyl esters of arylsulfonylamidophosphoric acids 1

SOURCE: Zhurnal obshchey khimii, v. 35, no. 3, 1965, 534-544

TOPIC TAGS: organic synthetic process, ester, phosphoric acid, organic sulfur compound, organic nitrogen compound, organic salt

ABSTRACT: Dialkyl esters of arylsulfonylamidophosphoric acids with higher alkyl radicals were synthesized and investigated as complex formers and extraction reagents for various metals. Dialkyl esters of arylsulfonylamidophosphoric acids, possessing the properties of monobasic acids, were synthesized by the action of trichlorophosphazenesulfonylaryls on higher aliphatic alcohols or by the action of dichlorides of arylsulfonylamidophosphoric acids on higher sodium alcoholates. The solubility of the sodium salts of higher alkyl esters of arylsulfonylamidophosphoric acids in water decreases, while that in organic solvents increases with increasing molecular weight of the alkyls. Sodium salts of the higher dialkyl esters of arylsulfonylamidophosphoric acids are

Card 1/2

L 28875-66

ACC NR: AP6018835

0
extracted from aqueous solutions by organic solvents. Extraction takes place only from neutral or alkaline solutions. Under the action of sodium salts of higher dialkyl esters of arylsulfonylamidophosphoric acids on metal chlorides, sulfates, or nitrates in aqueous solutions, aluminum, barium, beryllium, ferrous and ferric, cadmium, calcium, magnesium, manganese, copper, nickel, strontium, and chromium salts of higher dialkyl esters of arylsulfonylamidophosphoric acids are produced; they are very sparingly soluble in water and readily soluble in organic solvents. In the synthesis of dialkyl esters of arylsulfonylamidophosphoric acids from tri-chlorophosphazosulfonylaryls and higher alcohols, higher monoalkyl esters of the arylsulfonylamidophosphoric acids $(ArSO_2NHPO(OH)(OR))$ are formed and are isolated in the form of the disodium salts. TITLE: Properties and structural strength of pipes manufactured from steel 12Kh1M1F

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 3, 1966, 54-55

TOPIC TAGS: PIPE, STRESS ANALYSIS, TEMPERING, alloy steel, chromium steel, molybdenum steel, vanadium steel, steel / 12Kh1M1F steel

ABSTRACT: The effect of normalization, quenching, and tempering (followed by aging without and with an applied load) on the mechanical properties and structural strength of two thick-wall pipe specimens manufactured from steel 12Kh1M1F was investigated. The experimental results are presented in graphs and tables (see Fig. 1).

Fig. 1. Long-range strength of normalized steel 15Kh1M1F. 1 - initial state; 2 - aged for 500 hrs; 3 - aged for 1000 hrs; 4 - aged for 3000 hrs; 5 - aged for 5000 hrs.

It was found that during aging of steel 12Kh1M1F a block type structure develops in the latter. The thermal stability data were treated by the method of I. A. Oding. The results of this analysis showed that the structural changes taking place in the normalized steel under usual working loads are negligible and have little influence on the accumulation of disaggregation nuclei. Title : Study of cadmium chloride complexes by means of anionites

Periodical : Zhur. fiz. khim. 29/11, 2042-2047, Nov 1955

Abstract : A new method for the determination of stability constants of complex anions by means of anions, provided the solution contains one complex ion and complex cations and molecules, is described. The method is based on the application of the effective mass law to the ion exchange. It is shown that the distribution of Cd between the anionite and the potassium chloride solution at an ion force close to one corresponds to a certain

PURPOSE: This collection of articles is intended for personnel in scientific institutions and schools of higher education and for physical metallurgists and physicists specializing in metals. It may also be useful to students of these fields.	
CONTENTS: The collection contains results of experimental and theoretical investigations carried out by schools of higher education and scientific research institutions in the field of the relaxation phenomena in metals and alloys. Several articles are devoted to the investigation of the internal-friction method of the decomposition of superaturated solid solutions. Also analyzed are the defects of the crystalline lattice, plastic deformations, high-temperature behavior of alloys, and creep. Problems of the relation between internal friction and low-temperature creep. Problems of the relation between internal friction and the investigation of power-generating products, and the mechanics of impact techniques are discussed. The collection also contains articles on the dynamic characteristics of materials, elastic properties, and the new alloy-formation method. No personalities are mentioned. References follow most articles. There are 365 references: 192 Soviet and 174 non-Soviet.

TITLE: A Study of the Sensitivity of Structural Steels to Overheating
(Izucheniye chuvstvitel'nosti konstruktsionnykh staley k peregrevu)

PERIODICAL: Metallovedeniye i term. obrabotka. Moscow, Metallurgizdat, 1958, pp 21-30

ABSTRACT: An investigation is made of the tendency of 15Kh2GNTA, 25Kh2GNTA, 30Kh2N2VA, and 30Kh3VA steels to overheat in the 900-1300°C temperature interval, and the possibility of correcting this tendency is studied. It is found that overheating may be corrected by normalization at 900-950°. The standard mechanical properties of the overheated and the normally treated metal are identical. The overheating effect is found in impact testing at -70°, in notch tensile testing at 8° notch angle and in fatigue testing; overheating reduces σ_k from 9 to 3.4 kgm/cm², σ_b from 106 to 68-77 kg/mm², and σ_{-1} by 3-6 kg/mm². The correction of overheated steel by

AUSFORMING OF CHROMIUM STEELS (USSR)

Kubyshkina, T. D., L. M. Pevzner, L. S. Fedotova, and M. F. Alekseyenko.
Metallovedeniye i termicheskaya obrabotka metallov, no. 4, Apr 1963, 32-35.
S/129/63/000/004/008/014

The effect of ausforming on mechanical properties of complex alloyed steels 1X12HEM2A or 3W961 (0.12% C, 11.3% Cr, 1.77% Ni, 1.60% W, 0.43% Mo, 0.27% V) and BHC-6 (0.25% C, 12.3% Cr, 1.64% Ni, 1.74% W, 1.96% Mo, 0.23% V) was investigated. Steel specimens 90 x 35 x 22 mm were austenitized at 1020°C, furnace-cooled to 550°C, rolled with 90% reduction to a thickness of 2.5 mm, and immediately oil-quenched. The table shows tensile strength σ_b , yield strength $\sigma_{0.2}$, elongation δ , and notch toughness a_k of ausformed and conventionally hardened steels in as-quenched condition and after tempering at 500°C for 2 hrs.

Card 1/3

AID Nr. 985-2 7 June

AUSFORMING OF CHROMIUM STEELS [Cont'd]

S/129/63/000/004/008/014

Steel	Condition	σ_b kg/mm ²	$\sigma_{0.2}$ kg/mm ²	δ %	α_k kg-m/cm ²
1X12HBMΦA	Ausformed	180.5	170.0	15.2	6.4
	Ausformed and tempered	173.5	167.0	13.9	8.6
	Quench hardened	147.0	127.5	15.8	
	Quench hardened and tempered	142.0	131.5	13.2	
	Ausformed	231.5	150.5	10.9	4.1
	Ausformed and tempered	220.5	171.0	13.5	6.8
BHC-6	Quench hardened	191.0	151.5	11.5	4.5
	Quench hardened and tempered	183.5	150.5	11.5	3.4

Thus, compared to conventional hardening, ausforming increases tensile and yield strength by approximately 20% without lowering ductility. It also makes

Card. 2/3

AID Nr. 985-2 7 June

AUSFORMING OF CHROMIUM STEELS [Cont'd]

S/129/63/000/004/008/014

the steel structure more stable; the softening of ausformed steels begins at temperatures well over 500°C. Both steels after conventional hardening are susceptible to temper brittleness; for example, tempering at 400-500°C lowers the notch toughness of BHC-6 steel to 2.5-3.0 kgm/cm². In the ausformed BHC-6 steel, however, notch toughness increases steadily with increasing tempering temperature up to 7 kgm/cm² at 500°C. Another special advantage of ausformed steels is high notch toughness at subzero temperatures; BHC-6 ausformed and tempered at 500°C has an average notch toughness at -70 to -196°C of over 7 and 4.0 kgm/cm², respectively. In conventionally hardened steel, notch toughness dropped to 1-1.5 kgm/cm² at -70°C. [WW]

TITLE: Carbide transformations in heat-resistant steel containing 12% Cr

SOURCE: Fazovyy sostav, struktura i svoystva legirovannykh staley i splavov
(Phase composition, structure, and properties of alloy steels and alloys).
Moscow, Izd-vo Mashinostroyeniye, 1965, 116-125

TOPIC TAGS: heat resistant steel, chrome steel, martensitic steel, steel phase
composition, carbide transformation, molybdenum steel, steel heat treatment,
steel mechanical property

ABSTRACT: Martensitic heat-resistant steels with 12% Cr contain the so-called
Me₂C phase, which has an Mo₂C-type structure and forms at low temperatures.
The chemical composition and temperature region of existence of this phase were
established in four steels containing 12% Cr but different amounts of carbon,
nickel, and molybdenum (see Table 1 of the Enclosure). X-ray structural analysis
of the anodic deposits isolated from these steels showed the presence, depending
upon the tempering conditions, of a single phase with an Mo₂C-type hexagonal
structure or the same phase containing Me₂₃C₆. The crystal lattice parameters

Card 1/3

L 45132-65

ACCESSION NR: AT5011346

6
of the Me_2X phase were found to be $a = 2.86 \text{ \AA}$, $c = 4.47 \text{ \AA}$, and chemical analysis showed that the main constituent of the phase is chromium. Hence, its main constituent is either Cr_2C or the alloyed carbonitride $Cr_2(C, N)$. Molybdenum, tungsten, and vanadium increase the stability and extend the temperature region of existence of the carbide Me_2C . It is most stable in steel 4. As the tempering is raised, the metastable carbide Me_2C dissolves partially or completely, and the alloying elements are bound in the more stable carbides $Me_{23}C_6$. The latter dissolve in the temperature interval of stability of Me_2C carbides. After long tempering at 550°C (100 hrs.), an intermetallic phase of type Fe_2W is formed in steel 4. The formation of highly dispersed carbides Me_2C raises the yield point and ultimate strength of the steel and retards the softening of steel in the course of short-term tempering. "N. V. Ivanova and K. V. Smirnova participated in the experimental part of the work." Orig. art. has: 5 tables.

TITLE: Phase composition and properties of heat-resistant steel containing 12% chromium

SOURCE: Stal', no. 5, 1965, 448-452

TOPIC TAGS: chromium steel, heat resistant steel, molybdenum steel, vanadium steel, tungsten steel

ABSTRACT: The effect of alloying elements on the phase composition and properties was studied in three types of chromium steel containing approximately 12% chromium, alloyed with molybdenum, tungsten, and vanadium. At low tempering temperatures, depending upon the duration of tempering, the metastable carbides Me_3C and Me_2C are formed. The Me_2C carbides (with Cr C as the main component) cause the secondary hardness of the steels. The temperature range of existence of Me_2C carbides widens as the molybdenum and tungsten content increases. An appreciable drop in the impact strength of such steels is observed when the dispersed carbides (par-

Card 1/2

L 1678-66

ACCESSION NR: AP5013232

particularly Me_2C_6) precipitate. In the course of tempering steels with a high molybdenum and tungsten content, all of the carbon gradually becomes fixed in the carbides, and this is followed by the formation of particles of the intermetallic phase $\text{Me}_2(\text{W}, \text{Mo})$. The formation of this phase causes a decrease in the impact strength. Orig. art. has: 8 tables.

ABSTRACT: The properties and structure of 1Kh12N2VMFA martensite steel are given. Its chemical composition is (in %): 0.12 C, 12 Cr, 1.5 Ni, 2 W, 0.25 V, and 0.4 Mo. This steel can operate for prolonged periods at temperatures to 600C. The introduction of nickel allows the formation of δ -ferrite to be avoided. Its best mechanical properties are achieved with quenching from a temperature corresponding to fairly complete dissolution of the carbon and alloy elements (from 1000--1020C in oil or in air, with tempering at 580 or 680C). In the hardened state, the steel has a hardness of HRC 44--46 (see Fig. 1). The magnetic and dilatometric methods were used to study the martensitic transformation in the steel. It was found that the displacement of the boundaries of <u>martensitic transformation</u> did not substantially increase the amount

Title : Experiment on combatting loss of appetite in patients suffering from tuberculosis of the lungs

Periodical : Vop. pit., 26-30, Jul/Aug 1955

Abstract : Selection of favorite dishes, changes in eating schedule, and certain other measures were found to be effective in increasing the appetite of patients suffering from tuberculosis of the lungs. Use of vegetable juices, and small amounts of natural grape wine also helped. Surgical treatment (thoracoplasty, collapsing of the lungs) lowered the tuberculin intoxication and often improved the appetite. One table; no references.

9
nitric and sulfuric acid at 30 - 40C, was developed at the Voronezh shinnyy zavod (Voronezh Tire Plant). Polyphenyleneethylenes (containing 2.4, 3.0, 4.1, and 5.4% nitrogen) and polyethylphenyleneethylenes (4.9% nitrogen) were synthesized and tested in tread stocks with an SKS-30ARKM base containing PM-70 carbon black and with an NK base containing a combination of channel gas black and PM-70 black. In mixtures based on SKS-30ARKM, addition of the nitro derivatives markedly increases the hardness and the modulus at 300% elongation, and causes a certain increase in the strength of the vulcanizates. In mixtures based on NK, the synthesized products raise the modulus at 300% elongation (by 10 - 20%) and the hardness. Orig. art. has: 4 figures and 1 table.

TITLE: Certain regularities in marrow wasting in rats injured by gamma radiation 19

SOURCE: Radiobiologiya, v. 3, no. 3, 1963, 389-392

TOPIC TAGS: marrow wasting, radiation sickness, quantitative marrow cell count

ABSTRACT: Little is known about the wasting process of blood-forming tissue, especially marrow, in radiation sickness. This study differs from others because it uses a quantitative marrow cell count method to measure wasting. White rats were exposed to a cobalt gamma source in doses of 150, 400, 750, and 5,000 r. Dose power was 290-302 r/min. After exposure marrow cell counts at the hip were made at regular intervals from .5 hr to 72 hrs. Results are summarized in Figs. 1 and 2. Marrow wasting, it was found, can be divided into three phases. The first phase lasts 4 hrs and the number of cells does not change. The second phase lasts 2-3 hrs and the number of cells decreases depending on radiation dose (in the range from 400 to 5,000 r the dependence can be expressed by a power function). The third phase has a duration depending on radiation dose and the number of cells also decreases according to the same power function except for the 150 r dose. For

Card 1/2

I 11241-63
ACCESSION NR: AP3001063

small dose radiation (150-400 r) the second phase is most important because 52% to 77% of the total decrease in number of cells takes place. For large dose radiation (750-5,000 r) the second and third phases are of nearly equal importance because decrease in the number of cells is about 51% to 60% in the second phase and 49% to 40% in the third phase. TITLE: Disturbance of cell regeneration in the bone marrow of rats exposed to ionizing radiation

PERIODICAL: Meditsinskaya radiologiya, v. 8, no. 2, 1963, 35-41

TEXT: The above problem was studied in view of lack of publications concerned with the effect of radiation on the bone marrow. The animals were exposed to whole-body γ -irradiation at 305 r/min, the total dose being 400 r. The rats were then decapitated on the 1st, 3rd, 5th, 7th, 9th, 15th, 20th and 30th day after irradiation and the mitotic index, the development of chromosome observations, the total content of myeloid cells and individual cellular regenerations in the bone marrow were measured. The mitotic index fell sharply on the 1st day and then rose rapidly to a maximum on the 7th day; a second shallow minimum on the 15th day was then followed by a gradual rise. The number of cells of the bone marrow

Card 1/2

Disturbance of cell regeneration ...

S/241/63/008/002/004/006
D243/D307

was not however fully related to the above changes. Chromosome aberrations rose sharply on the 1st day after irradiation and then rapidly decreased, with a slight maximum on the 7th day. The mitotic activity of erithropoietic cells showed a sharp rise from the 3rd day after dosing, indicating regeneration of these cells. It is concluded that the myeloid cells of the bone marrow, which divided with manifestation of chromosome aberrations, gave rise to non-viable daughter cells and perished rapidly. There are 1 figure and 3 tables.

Title : Formation of Tubercles on the Roots of Soy in a
Vegetation Experiment.

Orig Pub: Agrobiologiya, 1956, No 6, 29-34.

Abstract: In experiments of the Institute of Genetics
AS USSR with soy and lupine, the possibility was
studied of formation of tubercles on the roots
of these plants in soils on which neither had
ever been cultivated. Before sowing, the seeds
were sterilized with sulfuric acid (1.5 minutes
in acid of specific weight 1.84). In the course
of the vegetative period each crop was cultivated

twice, so that for two years the experiments were variants with sowing four times in the same containers. Both in the first and second year of the experiment, tubercles were not formed on the roots of the soy and lupine. They did not appear with sowing with non-sterile seeds. Tubercles are normally formed in the first year on these soils in peas and beans. For the creation of a poorer base, in the second year half the soil was mixed with river sand in 50% of the vessels before sowing. In addition, an additional experiment was established with cultivation of plants on pure sand. In these variants, the tubercles were formed on the roots of the lupine and soy; in the soy, they were a non-typical form for this plant. With repeated cultiva-

tion of the soy in the vessel with sand, in which the roots with tubercles remained from the primary sowing, tubercles appeared, on the whole typical for soy, the size of a pea grain and stronger. Tubercles were formed in plants which were not distinguished by good development, possessed yellow-colored leaves. No tubercles appeared in the roots of well-developed plants. -- G. N. Chernov.

FEDOTOVA, M. S.
 Flocculation of bentonite suspensions to make sand impermeable to water. M. S. Fedotova and E. A. Pospelova (M. V. Lomonosov State Univ., Moscow). *Doklady Akad. Nauk S.S.S.R.* 94, 11:59-62 (1954).—The highly stable, thixotropic suspensions (with 3 to 8% solid material) of Oglaninsk Na bentonite are flocculated by dil. solns. of $AlCl_3$ (e.g., 0.0003% to 0.05 and 0.10% of the salt). The rate of filtration through the bentonite-treated sand corresponds to $\log s = a + \gamma \log t$, in which a is experimentally detd., γ is measured by the tan function of the slope angles for the parallel lines of the graph of this equation, s is vol. of filtrate, and t is time. To make sand less permeable to H_2O the highly dispersed bentonite suspension is impregnated completely into the loose sand, then the flocculating agent is added to ppt. the clay mineral particles on the surface of the sand grains. This effect is satisfactory only to a depth of about 5 cm. If the concns. (in g. equivalents) for the solns. of the chlorides of Na, K, Mg, Ca, Ba, and Al are plotted against the const. a (detd. for a filtration time of 10 min.), the efficiencies of the flocculation of $AlCl_3$, $MgCl_2$, and $NaCl$ are given by the ratio of the concns. 1:4:113. The lyotropic series $Na^+ < K^+ < Mg^{2+} < Ca^{2+} < Ba^{2+}$ is evidently valid. Additions of Na_2CO_3 more or less compen-

sate the flocculating effect of $AlCl_3$. By such mixed addns. the times of flocculation can be controlled. W. Eitel

TITLE: Development of new types of light-sensitive paper

SOURCE: Bumazhnaya promyshlennost', no. 12, 1965, 7-8

TOPIC TAGS: photosensitivity, paper, paper industry

ABSTRACT: New light-sensitive papers were developed, combining diazo compounds which had not been used previously in the paper industry and a new type of paper base. $ZnCl_2$ salts of diazotized 4-N-ethyl-N- β -hydroxyethylaniline and 4-diazophenylmorpho-

line gave good results on quality paper prepared from highly bleached cellulose, TiO_2 filler, and optical brightener. Commercial Fe-containing $ZnCl_2$ was shown to impair

quality by interaction with 2,3-dihydroxynaphthalene-6-sulfonic acid, a component of the light-sensitive solution. Temperature controlled drying was required to prevent decomposition of diazo compounds. Glycerol, being in short supply, was replaced by a 2:1 amount of xylitol. The new dry developing papers gave sharp contrasts and high
